Air Quality Programme 2030

As requested in the NEC directive

- A delegation with representatives from ministries, research institutes and industry to make the national programme during 2018
- Calculation of baseline (CLE) emission projection not finished, but looks like all other targets except ammonia could be met without additional measures
- Possibly additional PaMs to improve air quality and reduce health impacts
 - Domestic wood combustion: Information campaigns, sauna stove measures
 - Road dust: Street cleaning, dust binding, studded tire restrictions
 - However, they are most likely to be descriptive and voluntary
 - **Prioritisation of black carbon** when taking PaMs to reduce PM2.5

Damage cost model: Contents

- Motivation for the work
- Modelling steps and the result
- Observations

Motivation

- Work requested by the Finnish Ministry of the Environments
 - What damage costs should be used when planning air quality policies in Finland?
 - What are the differences in damage costs between high/low altitude and urban/non-urban sources
 - How valid are costs from other European studies in Finnish impact assessments
- We* wanted to make the model as simple to use as possible for all interested parties

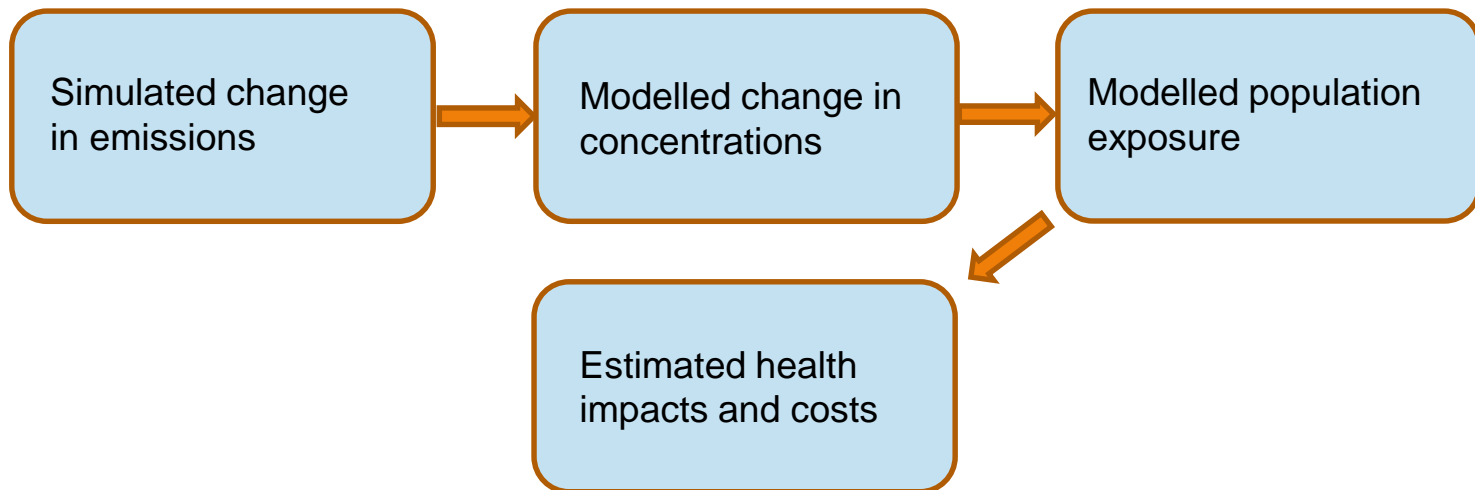

* Finnish Environment Institute, Finnish Meteorological Institute & National Institute for Health and Welfare

Monetary valuation of environmental impacts is challenging

Modelling the health impacts caused by changing PM2.5 concentrations

- Studied pollutants: PPM2.5 and the most important precursors for secondary particles (SO₂, NO_x, NH₃)
- Impacts and costs calculated using impact pathway approach

Emissions and resulting concentrations

- All Finnish emissions calculated for 2015 and spatially distributed into a 250 m x 250 m grid
 - Distribution by plant locations, land/road use data, building registers, climate conditions and degree of urbanization
- Dispersion modelling
 - Source-receptor matrices for low-altitude PPM2.5 emissions (250 m x 250 m)
 - Atmospheric dispersion modelling (SILAM) for the rest (5 km x 5 km)
 - Includes also other relevant pollutants as well as long-range transboundary pollutants

Industry and power plants, SO₂ → PM_{2.5}
SILAM model

Population exposure and health impacts

- Population data (250 m x 250 m grid) compared to changes in concentrations
- Included health impacts:
 - Premature mortality
 - Chronic bronchitis, asthma
 - Hospital treatment (heart/respiratory diseases)
 - Missed working days/reduced efficiency
- Premature mortality
 - Two common methods used*:
 - VOLY (Value of Life Year)
 - VSL (Value of Statistical Life)

*From the NewExt study

Population density

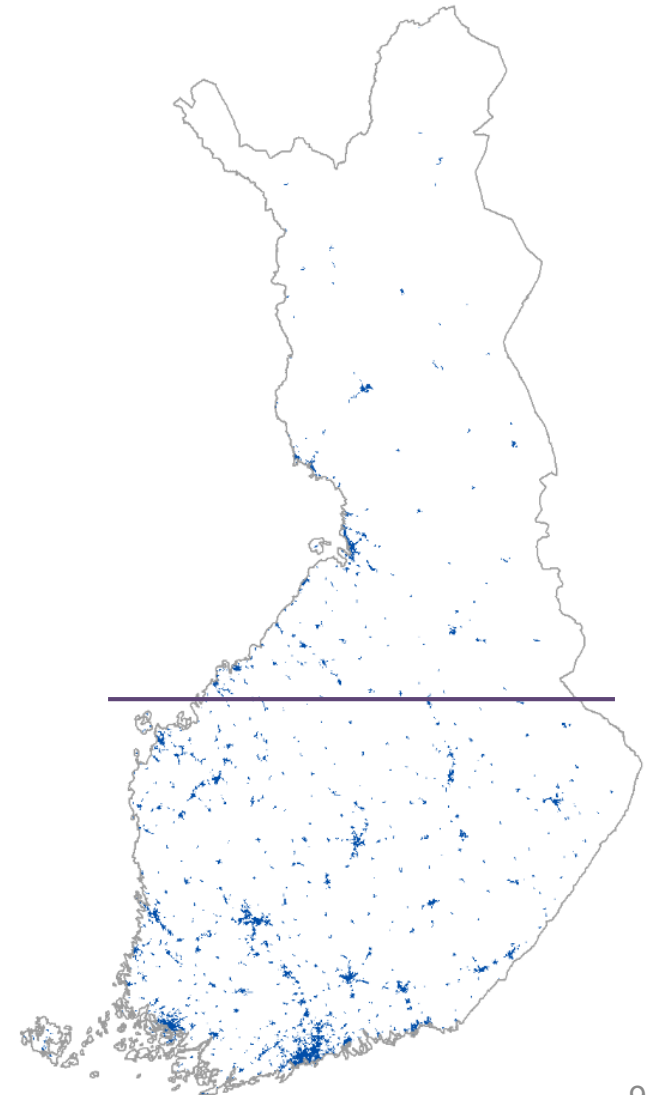

Urban/non-urban areas

Urban area

- At least 200 residents in a grid cell
- Buildings no further than 200m apart

Town of Ivalo, urban area.
www.mapio.net

Damage cost model

Monetary benefits from reduction of emissions (1000€/ton)

Low emission height	Location of emission reduction	
	Urban area	Non-urban area
Road transport, primary PM _{2.5}	140 ¹ (80 ² –320 ³)	13 (7.6–31)
Non-road & machinery, Primary PM _{2.5}	170 (100–390)	5.0 (2.8–11)
Residential houses, wood stoves & sauna stoves Primary PM _{2.5}	70 (40–160)	8.7 (4.8–19)
	All of Finland	
Recreational houses, wood stoves & sauna stoves, Primary PM _{2.5}	5.5 (3.1–13)	
Residential houses, wood boilers, Primary PM _{2.5}	12 (6.6–27)	
Road transport, NO _x -> secondary PM _{2.5}	0.82 (0.46–1.8)	
Agriculture, NH ₃ -> secondary PM _{2.5}	1.2 (0.70–2.8)	
High stacks	Southern Finland	Northern Finland
Industry & power plants, Primary PM _{2.5}	10 (5.8–24)	5.7 (3.2–13)
	All of Finland	
Industry & power plants SO ₂ -> secondary PM _{2.5}	1.3 (0.73–3.1)	
Industry & power plants, NO _x -> secondary PM _{2.5}	0.43 (0.24–1.0)	

¹ VOLY average (Value Of Life Year) 160 000 €

² VOLY median (Value Of Life Year) 69 000 €

³ VSL average (Value of Statistical Life) 2,65 milj. €.

Comparison to earlier studies

Health damage cost for ton of PM2.5

Study	Emission source	Unit cost
EEA, 2014	High stacks	16 000€
Brandt et al., 2013	High stacks	23 000€
Preiss et al., 2008	High stacks	12 000€
Our study	High stacks, Southern/Northern Finland	10 000/6000€
Bickel et al., 2003 (UNITE)	Traffic, Helsinki	526 000€
Gynther et al. 2012	Traffic, Finnish towns	23 000 – 680 000€
Our study	Traffic, Finnish urban areas	140 000€

- Reasonably good comparability with normalized parameters

Where should the model be used

- Expert work for policy support
 - National level strategies
 - Municipal level strategies
 - Individual plants?
- Challenges
 - Requires an estimate for the amount of emission reduction in tons
 - Gives average values
 - Not accurate in small-scale assessments
 - Only includes health impacts (and only part of them)
 - Cost for premature mortality "not up to date(?)"

- My takeaways from the study
 - Money talks, so these kind of tools are in demand
 - Other environmental impacts should be included somehow
 - NEEDs project shows that biodiversity costs are relevant
 - Valuing loss of life makes things difficult
 - Recent studies show much higher VSL values than the high end of our range
 - Everything is underestimated, this message is probably lost in the policy making process
 - Even with an easy user interface, a lot of expertize is needed to actually use the model
 - Maybe some additional help for the user to make calculations, e.g. "1000 stoves produce x ton of PM2.5 emissions annually"

Observations

2/2

- Questions
 - What cost should we use for premature death?
 - How should ecosystem damage be included?

Thanks!
